#### MARKOV CHAIN MONTE CARLO

We are interested in a distribution  $\pi(x) = \frac{f(x)}{Z}$ 

(e.g. want the mean, quantiles etc.)

Monte Carlo: approximate with independent samples from  $\pi$ 

MCMC: produce dependent samples via a Markov chain

$$x_0 \to x_1 \to x_2 \to x_3 \to \cdots \to x_{N-1} \to x_N$$

Use dependent samples to approximate integrals w.r.t.  $\pi(x)$ :

$$\frac{1}{N}\sum_{i=1}^{N}g(x_i)\approx \mathbb{E}_{\pi}[g]$$
 as

Let  $\mathcal{T}(x_i \to x_{i+1})$  be the Markov transition kernel. We require:

Let  $\mathcal{T}(x_i \to x_{i+1})$  be the Markov transition kernel. We require:

•  $\pi$  is a stationary distribution of  $\mathcal{T}$ :

$$\pi(x) = \int_{\mathcal{X}} \pi(y) \mathcal{T}(y \to x) \mathrm{d}y$$

Let  $\mathcal{T}(x_i \to x_{i+1})$  be the Markov transition kernel. We require:

•  $\pi$  is a stationary distribution of T:

$$\pi(x) = \int_{\mathcal{X}} \pi(y) \mathcal{T}(y \to x) \mathrm{d}y$$

Also require that  $\mathcal{T}$  be

 $\cdot$  irreducible: not stuck to some part of  ${\mathcal X}$  forever

Let  $\mathcal{T}(x_i \to x_{i+1})$  be the Markov transition kernel. We require:

•  $\pi$  is a stationary distribution of T:

$$\pi(x) = \int_{\mathcal{X}} \pi(y) \mathcal{T}(y \to x) dy$$

Also require that  ${\mathcal T}$  be

- $\cdot$  irreducible: not stuck to some part of  $\mathcal X$  forever
- aperiodic: not stuck to some part of  $\mathcal X$  for e.g. even iterations. Can fix this with a 'lazy' Markov chain that allows self-transitions.

Let  $\mathcal{T}(x_i \to x_{i+1})$  be the Markov transition kernel. We require:

•  $\pi$  is a stationary distribution of  $\mathcal{T}$ :

$$\pi(\mathsf{X}) = \int_{\mathcal{X}} \pi(\mathsf{y}) \mathcal{T}(\mathsf{y} \to \mathsf{X}) \mathrm{d}\mathsf{y}$$

Also require that  $\mathcal{T}$  be

- $\cdot$  irreducible: not stuck to some part of  $\mathcal X$  forever
- aperiodic: not stuck to some part of  $\mathcal X$  for e.g. even iterations. Can fix this with a 'lazy' Markov chain that allows self-transitions.

Finally, for infinite state-spaces (e.g. the real line), need an additional condition:

positive recurrent: revisits every neighborhood infinitely often

## **ERGODICITY**

With these conditions, our chain is *ergodic*For any initialization:

$$\frac{1}{N} \sum_{i=1}^{N} g(x_i) \to \mathbb{E}_{\pi}[g] \quad \text{as } N \to \infty \qquad \text{(Ergodicity)}$$

#### **ERGODICITY**

With these conditions, our chain is ergodic

For any initialization:

$$\frac{1}{N} \sum_{i=1}^{N} g(x_i) \to \mathbb{E}_{\pi}[g] \quad \text{as } N \to \infty$$
 (Ergodicity)

We eventually forget the arbitrary initialization.

Typically, we discard the first *B* burn-in samples.

#### **ERGODICITY**

With these conditions, our chain is ergodic

For any initialization:

$$\frac{1}{N} \sum_{i=1}^{N} g(x_i) \to \mathbb{E}_{\pi}[g] \quad \text{as } N \to \infty$$
 (Ergodicity)

We eventually forget the arbitrary initialization.

Typically, we discard the first *B* burn-in samples.

A good transition kernel has:

- · A short burn-in period.
- · Fast mixing (small dependence across samples).

#### MARKOV CHAIN MONTE CARLO

The Markov transition kernel  ${\mathcal T}$  must satisfy

$$\pi(x_{n+1}) = \int_{\mathcal{X}} \pi(x_n) \mathcal{T}(x_{n+1}|x_n) dx_n$$

#### MARKOV CHAIN MONTE CARLO

The Markov transition kernel  ${\mathcal T}$  must satisfy

$$\pi(x_{n+1}) = \int_{\mathcal{X}} \pi(x_n) \mathcal{T}(x_{n+1}|x_n) dx_n$$

Usually, we enforce the stronger condition of detailed balance:

$$\pi(X_{n+1})\mathcal{T}(X_n|X_{n+1})=\pi(X_n)\mathcal{T}(X_{n+1}|X_n)$$

(Sufficient but not necessary)

#### THE PROBLEM

Given some probability density  $\pi(x) = f(x)/Z$ :

- How do you construct a transition kernel  $\mathcal T$  with  $\pi$  as it's stationary distribution?
- · How do you construct a good transition kernel

Focus of a huge literature.

#### THE PROBLEM

Given some probability density  $\pi(x) = f(x)/Z$ :

- How do you construct a transition kernel  $\mathcal T$  with  $\pi$  as it's stationary distribution?
- · How do you construct a good transition kernel

Focus of a huge literature.

One approach: the Metropolis-Hastings algorithm

The simplest and most widely applicable MCMC algorithm. Featured in Dongarra & Sullivan (2000)'s list of top 10 algorithms.

A random walk algorithm

Choose a proposal distrib.  $q(x_{new}|x_{old})$ . E.g.  $x_{new} \sim \mathcal{N}(x_{old}, \sigma^2 l)$ 

A random walk algorithm

Choose a proposal distrib.  $q(x_{new}|x_{old})$ . E.g.  $x_{new} \sim \mathcal{N}(x_{old}, \sigma^2 I)$ 

Initialize chain at some starting point  $x_0$ .

# Repeat:

- Propose a new point  $x^*$  according to  $q(x^*|x_n)$ .
- Define  $\alpha = \min\left(1, \frac{\pi(x^*)q(x_n|x^*)}{\pi(x_n)q(x^*|x_n)}\right) = \min\left(1, \frac{f(x^*)q(x_n|x^*)}{f(x_n)q(x^*|x_n)}\right)$
- Set  $x_{n+1} = x^*$  with probability  $\alpha$ , else  $x_{n+1} = x_n$ .

A random walk algorithm

Choose a proposal distrib.  $q(x_{new}|x_{old})$ . E.g.  $x_{new} \sim \mathcal{N}(x_{old}, \sigma^2 I)$ 

Initialize chain at some starting point  $x_0$ .

# Repeat:

- Propose a new point  $x^*$  according to  $q(x^*|x_n)$ .
- Define  $\alpha = \min\left(1, \frac{\pi(x^*)q(x_n|x^*)}{\pi(x_n)q(x^*|x_n)}\right) = \min\left(1, \frac{f(x^*)q(x_n|x^*)}{f(x_n)q(x^*|x_n)}\right)$
- Set  $x_{n+1} = x^*$  with probability  $\alpha$ , else  $x_{n+1} = x_n$ .

#### Comments:

- Do not need to calculate the normalization constant Z.
- Accept/reject steps ensure this has the correct distribution.

A random walk algorithm

Choose a proposal distrib.  $q(x_{new}|x_{old})$ . E.g.  $x_{new} \sim \mathcal{N}(x_{old}, \sigma^2 I)$ 

Initialize chain at some starting point  $x_0$ .

# Repeat:

#### Comments:

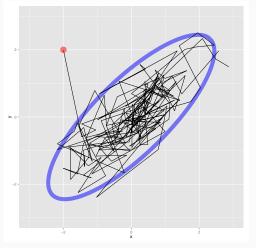

- Do not need to calculate the normalization constant Z.
- Accept/reject steps ensure this has the correct distribution.
- · On rejection, keep old sample (i.e. there will be repetition)

For a symmetric proposal  $(q(x^*|x_n) = q(x_n|x^*))$ :

$$\alpha = \min\left(1, \frac{f(x^*)}{f(x_n)}\right)$$

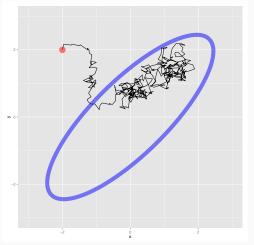

The Metropolis algorithm.

How do we chose the proposal variance?

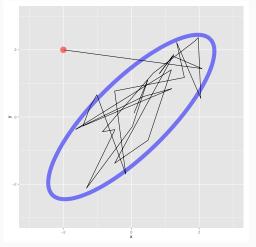

$$\sigma^2 =$$

How do we chose the proposal variance?

$$\sigma^2 = .$$

How do we chose the proposal variance?

$$\sigma^2 = 5$$

First, what is the transition kernel  $\mathcal{T}(x_{n+1}|x_n)$ ?

First, what is the transition kernel  $\mathcal{T}(x_{n+1}|x_n)$ ?

Prob. of moving from  $x_n$  to  $x_{n+1}$  is  $\alpha(x_{n+1}, x_n)q(x_{n+1}|x_n)$ .

First, what is the transition kernel  $\mathcal{T}(x_{n+1}|x_n)$ ?

Prob. of moving from  $x_n$  to  $x_{n+1}$  is  $\alpha(x_{n+1}, x_n)q(x_{n+1}|x_n)$ .

Prob. of accepting move at  $x_n$  is  $\alpha(x) = \int_{\mathcal{X}} \alpha(y, x_n) q(y|x_n) dy$ .

First, what is the transition kernel  $\mathcal{T}(x_{n+1}|x_n)$ ?

Prob. of moving from  $x_n$  to  $x_{n+1}$  is  $\alpha(x_{n+1}, x_n)q(x_{n+1}|x_n)$ .

Prob. of accepting move at  $x_n$  is  $\alpha(x) = \int_{\mathcal{X}} \alpha(y, x_n) q(y|x_n) dy$ .

Prob. of rejection at  $x_n$  is  $r(x_n) = 1 - \alpha(x_n)$ .

First, what is the transition kernel  $\mathcal{T}(x_{n+1}|x_n)$ ?

Prob. of moving from  $x_n$  to  $x_{n+1}$  is  $\alpha(x_{n+1}, x_n)q(x_{n+1}|x_n)$ .

Prob. of accepting move at  $x_n$  is  $\alpha(x) = \int_{\mathcal{X}} \alpha(y, x_n) q(y|x_n) dy$ .

Prob. of rejection at  $x_n$  is  $r(x_n) = 1 - \alpha(x_n)$ .

We then have:

$$\mathcal{T}(x_{n+1}|x_n) = \alpha(x_{n+1}, x_n)q(x_{n+1}|x_n) + r(x_n)\delta(x_n = x_{n+1})$$

First, what is the transition kernel  $\mathcal{T}(x_{n+1}|x_n)$ ?

Prob. of moving from  $x_n$  to  $x_{n+1}$  is  $\alpha(x_{n+1}, x_n)q(x_{n+1}|x_n)$ .

Prob. of accepting move at  $x_n$  is  $\alpha(x) = \int_{\mathcal{X}} \alpha(y, x_n) q(y|x_n) dy$ .

Prob. of rejection at  $x_n$  is  $r(x_n) = 1 - \alpha(x_n)$ .

We then have:

$$\mathcal{T}(x_{n+1}|x_n) = \alpha(x_{n+1}, x_n)q(x_{n+1}|x_n) + r(x_n)\delta(x_n = x_{n+1})$$

We want to show detailed balance:

$$\pi(X_n)\mathcal{T}(X_{n+1}|X_n) = \pi(X_{n+1})\mathcal{T}(X_n|X_{n+1})$$

Detailed balance:  $\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_{n+1})\mathcal{T}(x_n|x_{n+1})$ 

Consider the LHS:

$$\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_n)\left(\alpha(x_{n+1},x_n)q(x_{n+1},x_n) + r(x_n)\delta(x_n = x_{n+1})\right)$$

Detailed balance:  $\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_{n+1})\mathcal{T}(x_n|x_{n+1})$ 

Consider the LHS:

$$\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_n) \left(\alpha(x_{n+1},x_n)q(x_{n+1},x_n) + r(x_n)\delta(x_n = x_{n+1})\right)$$

The first term is: 
$$\frac{f(x_n)}{Z} \min \left(1, \frac{f(x_{n+1})q(x_n|x_{n+1})}{f(x_n)q(x_{n+1}|x_n)}\right) q(x_{n+1}|x_n)$$

Detailed balance:  $\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_{n+1})\mathcal{T}(x_n|x_{n+1})$ 

Consider the LHS:

$$\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_n) \left(\alpha(x_{n+1},x_n)q(x_{n+1},x_n) + r(x_n)\delta(x_n = x_{n+1})\right)$$

The first term is: 
$$\frac{f(x_n)}{Z} \min \left( 1, \frac{f(x_{n+1})q(x_n|x_{n+1})}{f(x_n)q(x_{n+1}|x_n)} \right) q(x_{n+1}|x_n)$$

$$= \frac{1}{Z} \min \left( f(x_n)q(x_{n+1}|x_n), f(x_{n+1})q(x_n|x_{n+1}) \right)$$

Detailed balance:  $\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_{n+1})\mathcal{T}(x_n|x_{n+1})$ 

Consider the LHS:

$$\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_n) \left(\alpha(x_{n+1},x_n)q(x_{n+1},x_n) + r(x_n)\delta(x_n = x_{n+1})\right)$$

The first term is: 
$$\frac{f(x_n)}{Z} \min \left( 1, \frac{f(x_{n+1})q(x_n|x_{n+1})}{f(x_n)q(x_{n+1}|x_n)} \right) q(x_{n+1}|x_n)$$

$$= \frac{1}{Z} \min \left( f(x_n)q(x_{n+1}|x_n), f(x_{n+1})q(x_n|x_{n+1}) \right)$$

First term of RHS has this form too.

Detailed balance:  $\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_{n+1})\mathcal{T}(x_n|x_{n+1})$ 

Consider the LHS:

$$\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_n) \left(\alpha(x_{n+1},x_n)q(x_{n+1},x_n) + r(x_n)\delta(x_n = x_{n+1})\right)$$

The first term is: 
$$\frac{f(x_n)}{Z} \min \left( 1, \frac{f(x_{n+1})q(x_n|x_{n+1})}{f(x_n)q(x_{n+1}|x_n)} \right) q(x_{n+1}|x_n)$$

$$= \frac{1}{Z} \min \left( f(x_n)q(x_{n+1}|x_n), f(x_{n+1})q(x_n|x_{n+1}) \right)$$

First term of RHS has this form too.

For the second term,  $r(x_n)\delta(x_n=x_{n+1})=r(x_{n+1})\delta(x_{n+1}=x_n)$ 

Detailed balance:  $\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_{n+1})\mathcal{T}(x_n|x_{n+1})$ 

Consider the LHS:

$$\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_n) \left(\alpha(x_{n+1},x_n)q(x_{n+1},x_n) + r(x_n)\delta(x_n = x_{n+1})\right)$$

The first term is: 
$$\frac{f(x_n)}{Z} \min \left( 1, \frac{f(x_{n+1})q(x_n|x_{n+1})}{f(x_n)q(x_{n+1}|x_n)} \right) q(x_{n+1}|x_n)$$

$$= \frac{1}{Z} \min \left( f(x_n)q(x_{n+1}|x_n), f(x_{n+1})q(x_n|x_{n+1}) \right)$$

First term of RHS has this form too.

For the second term,  $r(x_n)\delta(x_n=x_{n+1})=r(x_{n+1})\delta(x_{n+1}=x_n)$ 

Thus, 
$$\pi(x_n)\mathcal{T}(x_{n+1}|x_n) = \pi(x_{n+1})\mathcal{T}(x_n|x_{n+1})$$

# GIBBS SAMPLING

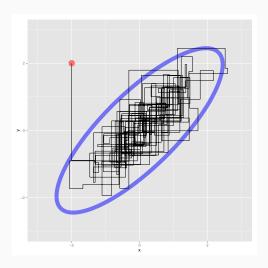

Consider a Markov chain over a set of variables  $(x_1, \dots, x_d)$ .

Gibbs sampling cycles though these sequentially (or randomly). At the *i*th step, it updates  $x_i$  conditioned on the trest:

$$X_i \sim \pi(X_i|X_1,\ldots,X_{i-1},X_{i+1},\ldots,X_n) = \pi(X_i|\mathbf{X}_{\setminus i})$$

Often these conditionals have a much simpler form than the joint.

## **GIBBS SAMPLING**

## DETAILED BALANCE FOR THE SEQUENTIAL GIBBS SAMPLER

Does it satisfy stationarity?

Does it satisfy irreducibility?

Is it aperiodic?

### DETAILED BALANCE FOR THE RANDOMIZED GIBBS SAMPLER

Suppose we update component i with prob.  $\rho_i$ . Let  $\mathbf{x}$  and  $\mathbf{x}'$  differ only in component i. Then:

$$\mathcal{T}(\mathbf{x}'|\mathbf{x}) = \rho_i \pi(\mathbf{x}_i'|\mathbf{x}_{\setminus i})$$

Also

$$\pi(\mathbf{x})\mathcal{T}(\mathbf{x}'|\mathbf{x}) = \pi(\mathbf{x})\rho_i\pi(\mathbf{x}'_i|\mathbf{x}_{\setminus i})$$
$$= \pi(\mathbf{x}_{\setminus i})\pi(\mathbf{x}_i|\mathbf{x}_{\setminus i})\rho_i\pi(\mathbf{x}'_i|\mathbf{x}_{\setminus i})$$

From symmetry (or by calculating RHS), we have detailed balance.

Under mild conditions, Gibbs sampling is irreducible.

Under mild conditions, Gibbs sampling is irreducible.

Can break down under constraints. E.g. two perfectly couple variables.

Performance deteriorates with strong coupling between variables.

Poor mixing due to coupled variables is always a concern.

Under mild conditions, Gibbs sampling is irreducible.

Can break down under constraints. E.g. two perfectly couple variables.

Performance deteriorates with strong coupling between variables.

Poor mixing due to coupled variables is always a concern.

Advantages: Simple, with no free parameters.

Under mild conditions, Gibbs sampling is irreducible.

Can break down under constraints. E.g. two perfectly couple variables.

Performance deteriorates with strong coupling between variables.

Poor mixing due to coupled variables is always a concern.

Advantages: Simple, with no free parameters.

Often, conditional independencies in a model along with suitable conjugate priors allow efficient 'blocked-Gibbs samplers'.

#### GIBBS SAMPLING

More generally, Gibbs sampling can update more than one component at each step.

E.g. consider a Markov chain over 5 variables  $(x_1, x_2, x_3, x_4, x_5)$ .

Alternately updating  $x_1, x_2 | x_3, x_4, x_5$ , and then  $x_3, x_4, x_5 | x_1, x_2$  form a correct Gibbs sampler

• If simulating these conditionals is easy, this can be more efficient than naively sampling one component at a time.

#### GIBBS SAMPLING

More generally, Gibbs sampling can update more than one component at each step.

E.g. consider a Markov chain over 5 variables  $(x_1, x_2, x_3, x_4, x_5)$ .

Alternately updating  $x_1, x_2 | x_3, x_4, x_5$ , and then  $x_3, x_4, x_5 | x_1, x_2$  form a correct Gibbs sampler

• If simulating these conditionals is easy, this can be more efficient than naively sampling one component at a time.

Can also have overlaps: e.g. update  $x_1, x_2, x_3 | x_5$ , and then  $x_3, x_4, x_5 | x_1, x_2$  form a correct Gibbs sampler

Convince yourself this is correct

# BACK TO THE MIXTURE OF GAUSSIANS (MOG)

Observations come from one of K components

- · each component is a Gaussian
- Component c has parameters  $\theta_c = (\mu_c, \Sigma_c)$ , its mean and covariance

To generate the *i*th observation:

$$c_i \sim \pi$$
 Sample it's cluster assignment  $x_i \sim \mathcal{N}(x_i | \mu_{c_i}, \Sigma_{c_i})$  Sample it's value

# BACK TO THE MIXTURE OF GAUSSIANS (MOG)

Observations come from one of K components

Given data X, how did we estimate the parameters  $\pi$ ,  $\{\mu_c, \Sigma_c\}$ ?

What does a Bayesian approach involve?

### BAYESIAN INFERENCE FOR MOG

Place a prior over  $\pi$ : conjugate is a Dirichlet prior Place a prior over the cluster parameters  $\theta_{c}=(\mu_{c},\Sigma_{c})$ : conjugate is the normal inverse-Wishart distribution.

### BAYESIAN INFERENCE FOR MOG

Place a prior over  $\pi$ : conjugate is a Dirichlet prior

Place a prior over the cluster parameters  $\theta_c = (\mu_c, \Sigma_c)$ : conjugate is the normal inverse-Wishart distribution.

Given data  $X = \{x_1, \dots, x_N\}$ , we want to sample from the distribution  $p(\pi, \{\mu_c, \Sigma_c\}_{c=1}^K | X)$ 

## BAYESIAN INFERENCE FOR MOG (CONTD.)

We will sample from the distribution  $p(C, \pi, \{\mu_C, \Sigma_C\}_{C=1}^K | X)$ , including the cluster assignments  $C = \{c_1, \dots, c_N\}$ .

We do this by Gibbs sampling

## BAYESIAN INFERENCE FOR MOG (CONTD.)

We will sample from the distribution  $p(C, \pi, \{\mu_C, \Sigma_C\}_{C=1}^K | X)$ , including the cluster assignments  $C = \{c_1, \dots, c_N\}$ .

We do this by Gibbs sampling

How do we do this?

### GIBBS SAMPLING FOR MOG

Initialize MCMC chain, by randomly assigning observations to one of the *K* clusters.

Then, repeat:

- 1) Given cluster assignments C, sample  $\pi$  and  $\{\mu_{\rm C}, \Sigma_{\rm C}\}$
- These are simple conjugate distributions (think about this and HW 5)

### GIBBS SAMPLING FOR MOG

Initialize MCMC chain, by randomly assigning observations to one of the *K* clusters.

Then, repeat:

- 1) Given cluster assignments C, sample  $\pi$  and  $\{\mu_{\rm c}, \Sigma_{\rm c}\}$
- These are simple conjugate distributions (think about this and HW 5)
- 2) Given parameters, sample cluster assignments C.
- We did this for the case of the EM algorithm: just simulate from the cluster "responsibilities"
