Lecture 12: Data carpentry with tidyverse

STAT598z: Intro. to computing for statistics

Vinayak Rao

Department of Statistics, Purdue University

```r
In [ ]: options(repr.plot.width=5, repr.plot.height=3)
```

We will use a dataset of movies scraped off IMDB: [https://www.kaggle.com/deepmatrix/imdb-5000-movie-dataset](https://www.kaggle.com/deepmatrix/imdb-5000-movie-dataset)

- Available from the class website

```r
In [ ]: movies_orig <- read.csv('./Data/movie_metadata.csv')
movies <- movies_orig
# Can view this in RStudio using View(movies)
movies[1,]
```

```r
In [ ]: unique(movies$director_name)
```

```r
In [ ]: unique(movies$director_name[movies$imdb_score>8.5])
```

```r
In [ ]: (movies$movie_title[movies$imdb_score>9])
```

```r
In [ ]: library('tidyverse')
movies <- as_tibble(movies)
```

Most functions that works with dataframes works with tibbles

- functions in tidyverse require tibbles
- additionally, tibbles have some nice conveniences

```r
In [ ]: my_rnd <- tibble(x=rnorm(10), y = x+1, z = x>0)
print(my_rnd) # tibbles also print a bit more nicely
```

**The 'pipe' operator %>%**

tidyverse gets this from package purrr

- magrittr offers additional functionality
A side point on infix functions

%%func_name%% is syntax for infix (rather than prefix) functions:

```r
In [ ]: '%%plus%%' <- function(x,y) x+y
1 %%plus%% 2; %%plus%%(3,4)
```

%%>% pipes output of first function to first argument of the second

Can give more readable code. E.g. consider

```r
In [ ]: range(
movies$actor_1_facebook_likes[
    order(
        movies$imdb_score, decreasing = T
    )
)][1:10]
# range(movies$actor_1_facebook_likes[
#   order(movies$imdb_score, decreasing = T)][1:10])
```

Have to parse code from inside to outside.

```r
In [ ]: movies$imdb_score %>>%
    order(decreasing = T) %>>%
    movies$actor_1_facebook_likes[.]
%>>% #What are the arguments to '[]'?
 .[1:10] %>>%
    range
```

By default, output of function to left of %>>% is the first argument of the function to the right

Use . as placeholder if argument you are piping to is not the first

```r
In [ ]: 4 %>>% log(2) # log(4,2)
In [ ]: 4 %>>% log(2,.) # log(2,4)
```

Can pipe to multiple arguments

```r
In [ ]: 2 %>>% log(.+6,.) # log(8,2)
```

Pipes in pipes are possible (but be careful)

```r
In [ ]: 2 %>>% log(.+6 %>>% .^2 %>>% print,.) ; log(38,2)
```
tiyverse gets %>% from the purrr package

The magrittr package provides more such functions.

E.g. the T-pipe %T>% passes the LHS onwards

- useful for functions like plot where output isn't important

```r
In [ ]: library(magrittr); rnorm(100) %T>% hist %>% mean
```

http://www.fromthebottomoftheheap.net/2015/06/03/my-aversion-to-pipes/

https://cran.r-project.org/web/packages/magrittr/vignettes/magrittr.html

Our next package from tidyverse is dplyr

- filter: pick observations by values (rows)
- arrange: reorder rows
- select: pick variables (columns) by their names
- mutate: create new variables from existing variables
- summarise: summarise many values

The scope of each is determined by group_by

For a more thorough overview, look at R for Data Science

The filter filter() function

Select cleaner alternative to indexing with logicals and which

```r
In [ ]: deniro <- filter(movies, actor_1_name == "Robert De Niro")
deniro[,c('imdb_score','movie_title')]

In [ ]: deniro_good <- movies %>%
  filter(actor_1_name == "Robert De Niro",
         imdb_score > 8)
deniro_good[,c('imdb_score','movie_title')]
```
Multiple argument are equivalent to logical AND (&):

\[
\text{deniro_good} \leftarrow \text{filter(movies,actor_1_name == "Robert De Niro" \& imdb_score > 7)}
\]

Logical or's must be written using |

\[
\text{In [ ]: dnr_pcn<-movies \%\% filter((actor_1_name=="Robert De Niro") | (actor_1_name=="Al Pacino"), imdb_score > 7)}
\]

\[
\text{dnr_pcn[,c('actor_1_name','imdb_score','movie_title')]}
\]

The select() function

Unlike filter(), select() picks columns of a tibble

\[
\text{In [ ]: select(deniro_good, movie_title, imdb_score)}
\]

\[
\text{In [ ]: select(deniro_good, director_name:actor_2_name)[1:10]}
\]

Can also use - to eliminate columns:

\[
\text{In [ ]: select(deniro_good, -(director_name:actor_2_name))}
\]

Also includes convenience functions like contains("actor") and num_range("var",1:3)

The arrange() function

Orders rows in increasing order of any chosen column

- Additional columns can be provided to break ties
- desc() can be used to sort in decreasing order

Missing values always go at the end

\[
\text{In [ ]: movies \%\% arrange(desc(imdb_score),desc(gross)) \%\% select(movie_title, imdb_score, gross) \%\% [1:10,]}
\]

\[
\text{In [ ]: arrange(movies, imdb_score, gross) \%\% select(movie_title, imdb_score, gross) \%\% [1:10,]}
\]

\[
\text{In [ ]: tmp <- arrange(movies, desc(imdb_score), desc(gross))}
\]

The mutate() function

Creates new columns at the end of current data.frame
mutate can refer to functions just created

```r
movies %>% filter(country == "USA") %>%
  select(movie_title, imdb_score, gross, budget) %>%
  mutate(succ = gross/budget) %>%
  arrange(desc(succ)) %>%
  .[1:20]
```

distinct() is a useful function to remove repeated rows

- can provide column names as arguments for partial repetitions

transmute() is useful if we only care about the new column

**summarise() and group_by()**

Summarise collapses a dataframe to a single row:

```r
summarise(movies, score = mean(imdb_score))
```

Becomes very powerful in conjunction with group_by()

```r
top_dir <- movies %>%
  group_by(director_name) %>%
  summarise(score = mean(imdb_score)) %>%
  arrange(desc(score))
top_dir[1:15,]
```

n() is a convenient function to get number of elements

```r
top_dir <- movies %>%
  group_by(director_name) %>%
  summarise(count=n(), score = mean(imdb_score)) %>%
  arrange(desc(score)) %>%
  filter(count>=5)
top_dir
```

```r
yr_scr <- movies %>%
  group_by(title_year) %>%
  summarise(count=n(), score = median(imdb_score),
            ymin = quantile(imdb_score,.1),
            ymax=quantile(imdb_score,.9)) %>%
  arrange(desc(score)) %>%
  filter(count>=5)
```

```r
ggplot(yr_scr, aes(x=title_year, y = score)) +
  geom_line() +
  geom_errorbar(aes(ymin=ymin,ymax=ymax))
```
Can have nested groupings (can revert with ungroup())

```r
In [ ]: act_dir <- movies %>%
  group_by(actor_1_name,director_name) %>%
  distinct(movie_title, .keep_all = T) %>%
  summarise(num = n(), scr = mean(gross-budget),
  ttl = paste(movie_title, collapse=";")) %>%
  arrange(desc(scr)) %>%
  filter(num>2)
act_dir[1:20,]
```

Let's try something more complicated:

- Can we analyse scores/earnings across genres?

Things are actually a bit more complicated:

```r
In [ ]: levels(movies$genres)
#movies %>% select(movie_title, genres) %>% .[1:10,]

In [ ]: gnr_type <- as.character(levels(movies_orig$genres)) %>%
  strsplit('\\|') %>% #will see regular expressions later
  unlist %>% unique
gnr_type

In [ ]: movies <- movies_orig
movies[,gnr_type] <- F
movies$genres <- as.character(movies$genres)
movies[29:54]

In [ ]: for(ii in 1:nrow(movies)) { # Will look at better approaches
  movies[ii,gnr_type] <-
  gnr_type %in% strsplit(movies$genres[ii],\\|')[[1]]
}
colnames(movies)[38] <- "Sci fi"
colnames(movies)[51] <- "Reality TV"
colnames(movies)[53] <- "Film Noir"
colnames(movies)[54] <- "Game Show"
gnr_type <- colnames(movies)[29:54]
movies[1:10,29:54]

In [ ]: #lm(imdb_score ~ Action + Adventure, movies )
rslt <- lm(paste("gross -",
  (paste(gnr_type,collapse = '+')), movies)
rslt

In [ ]: movies$ntile <- ntile(movies$imdb_score,10)
movies %>% select(movie_title, ntile) %>% .[1:10,]
```

summarise_each let's one summarize multiple columns easily
```r
In [ ]:
gnr_frac <- movies %>%
  group_by(ntile) %>%
  select(Action:Game_Show) %>%
  summarise_each(funs(mean, sum))
gnr_frac
```

```r
In [ ]:
library('RColorBrewer')
gnr_frac %>%
gather('Genre', 'Count', Action:Game_Show) %>%
ggplot() +
geom_line(aes(x=ntile, y=Count, color=Genre, linetype=Genre),
  size=1) +
scale_linetype_manual(values=c(rep("solid", 12), rep("dashed",11),
  rep("twodash",3))) +
scale_color_manual(values=c(brewer.pal(12,"Set3"),
  brewer.pal(11,"Set3"), brewer.pal(3,"Set3"))) +
scale_y_log10()
```

```
mutate_each allows you to transform multiple columns

In [ ]:
gnr_frac %>% mutate_each(funs(. / sum(.)), Action:Game_Show)
```

### Generating tidy data

The `gather` function, allows you to combine multiple columns into 2 columns.

- turns wide data into tall data

Tall data is useful for e.g. ggplot

```r
In [ ]:
state_info <- as_tibble(state.x77)
(state_info[1:10,])
```

```r
In [ ]:
state_info %>%
gather(Illiteracy:`HS Grad`, key='InfoType',
  value='InfoValue') %>%
ggplot +
geom_smooth(aes(x=Income, y=InfoValue,color=InfoType))
```

```r
In [ ]:
movies %>%
  filter(country=="USA") %>%
  select(title_year, budget, gross) %>%
gather(budget,gross, key = 'type', value='amt') %>%
ggplot + geom_smooth(aes(x=title_year,y=log10(amt),
  group=type, color=type)) +
  facet_wrap(~type)
```

```r
In [ ]:
movies %>%
  filter(country=="USA") %>%
  select(title_year, budget, Action:Musical) %>%
gather(Action:Musical, key = 'type', value='amt') %>%
  filter(amt==TRUE) %>%
ggplot + geom_smooth(aes(x=title_year,y=log10(budget),
  group=type, color=type), se=F)
```
spread() does the opposite

- turns a tall data.frame into a wide one

Wide data is useful for e.g. lm

```
In [ ]: spread(state_tall, key = InfoType, value=InfoValue)
```

```
In [ ]: stdnt <- tibble(
    name = rep(c("Alice", "Bob"), each=4),
    semester = c("Spring","Fall","Spring","Fall","Spring","Fall","Spring","Fall"),
    gpa = c(3.2, 3.9, 3.1, 3.6, 3.1, 3.9, 3.3, 3.3)
)
stdnt
```

```
In [ ]: stdnt %>% spread(key=semester, value=gpa)
```

What if there are missing/extra values?

melt() and dcast() from package reshape are slightly more powerful

- however, tidyverse with dplyr should meet all your needs

Another useful pair of functions in separate() and unite()

```
In [ ]: tmp <- movies %>% separate(director_name,c("First","Last"),
    sep=" ")
```

Can control what to do with missing/extra elements:

```
tmp <- movies %>% separate(director_name,c("First","Last"), sep=" ", extra="merge", fill="left")
```

Regular expressions will allow more expressivity

unite() does the opposite

```
In [ ]: tmp <- unite(stdnt, yr_sm, year, semester)

In [ ]: spread(tmp, key=yr_sm, value=gpa)
```
